

Seizures can result from a primary central nervous system disorder or may be a manifestation of a serious underlying metabolic or systemic disorder. The distinction is important, since treatment must be directed at the underlying cause as well as control of the seizure.

A. Active Seizures

BLS

- 1. Initial Assessment/Care Protocol 01P
- 2. Protect the patient from injury. Place in the recovery position if no C-spine injury is suspected.
- 3. Open and maintain a patent airway (Protocol 7). Ventilate the respiratory depressed or apneic patient with Bag Valve Mask as needed.

ALS

- 4. Establish IV access Procedure 13
- 5. Administer **Versed (Midazolam) 0.1mg/kg IV/IO (max single dose 5 mg)**. This may be repeated *once* in 5 minutes if the seizure continues (total dose 10mg).
 - Note: The IM/IN (Intranasal) dose for Versed is doubled to **0.2 mg/kg** with the same max doses.
- 6. Obtain a blood glucose level. If the glucose is < 50 mg/d, refer to Protocol 36P

MCP

7. Additional administration of benzodiazepines.

B. Transport Criteria

- 1. Patients meeting the following criteria shall be transported ALS by Miami-Dade Fire Rescue:
 - a) First time seizures. (This includes febrile seizures)
 - b) Failure to regain consciousness between seizures or a long period of unconsciousness following a seizure.
 - c) Patients suffering multiple seizures in twenty-four hours.
- 2. All other seizure patients assessed as being stable by Fire-Rescue personnel may be released to BLS transportation.
